Homework 1: Data Types, Functions and Conditionals Due February 12, 11:59 pm Worth 10 points

Read this first. A few things to bring to your attention:

- 1. Start early! If you run into trouble installing things or importing packages, it's best to find those problems well in advance, not the night before your assignment is due!
- 2. Make sure you back up your work! I recommend, at a minimum, doing your work in a Dropbox folder or, better yet, using git, which is well worth your time and effort to learn.

Instructions on writing and submitting your homework.

Failure to follow these instructions will result in lost points. Your homework should be written in a jupyter notebook file. I have made a template available on Canvas, and on the course website at http:pages.stat.wisc.edu/~kdlevin/teaching/Spring2021/STAT679/hw_template.ipynb. You will submit, via Canvas, a .zip file called NetID_hwX.zip, where NetID is your NetID and X is the homework number. So, if I were to hand in a file for this, homework 1, it would be called kdlevin_hw1.zip. Contact the instructor if you have trouble creating such a file.

When I extract your compressed file, the result should be a directory, also called NetID_hwX. In that directory, at a minimum, should be a jupyter notebook file, called NetID.hwX.ipynb, where again NetID is your NetID and X is the number of the current homework. You should feel free to define supplementary functions in other Python scripts, which you should include in your compressed directory. So, for example, if the code in your notebook file imports a function from a Python file called supplementary.py, then the file supplementary.py should be included in your submission. In short, I should be able to extract your archived file and run your notebook file on my own machine. Please include all of your code for all problems in the homework in a single Python notebook unless instructed otherwise, and please include in your notebook file a list of any and all people with whom you discussed this homework assignment. Please also include an estimate of how many hours you spent on each of the sections of this homework assignment.

These instructions can also be found on the course web page at http:pages.stat.wisc.edu/~kdlevin/teaching/Spring2021/STAT679/hw_instructions.html. Please direct any questions to the instructor.

1 Warm up: Defining Simple Functions (2 points)

In this problem, you will get practice defining simple functions in Python.

1. Define a function called say_hi, which takes no arguments and prints the string Hello, world! when called.

2. Define a function called goat_pad, which takes a string as its only argument, and prints that string, prepended and appended with the string goat. So, goat_pad('bird') should produce the output

goat_pad('_') should produce the output

and so on. You may assume that the input is a string, so there is no need to perform any error checking in your function.

3. Define a function called print_n, which takes two arguments, a string s and an integer n (in that order), and prints the string n times, each on a separate line. You may assume that s is a string and that the integer n is non-negative.

2 Euclid's algorithm (2 points)

Euclid's algorithm¹ is a method for finding the greatest common divisor (GCD) of two numbers. Recall that the GCD of two numbers m and n is the largest number that divides both m and n.

- 1. The Wikipedia page above includes several pseudocode implementations of Euclid's algorithm. Choose one of these, and use it to implement a function gcd, which takes two integers as its arguments and returns their GCD. You may assume that both inputs are integers, so there is no need to include any error checking in your function. Note: this is one of the rare occasions where you have my explicit permission to look up your answer. Unless otherwise stated (e.g., as in this problem), looking up solutions on Wikipedia or in any other non-class resource will be considered cheating!
- 2. Use your function to evaluate the GCDs of the following pairs of numbers:
 - (a) 2020, 2021
 - (b) 1200, 300
 - (c) 5040, 60
- 3. What does your function do if one or both of its arguments are negative? Does this behavior make sense?

3 Approximating Euler's number e (3 points)

The base of the natural logarithm, e, is typically defined as the infinite sum

$$e = \sum_{k=0}^{\infty} \frac{1}{k!} = 1 + 1 + \frac{1}{2} + \frac{1}{6} + \frac{1}{24} + \dots,$$
 (1)

where k! denotes the factorial of k,

$$k! = k \cdot (k-1) \cdot (k-2) \cdot \cdots \cdot 3 \cdot 2 \cdot 1$$

¹https://en.wikipedia.org/wiki/Euclidean_algorithm

where we define 0! = 1 by convention.² In this problem, we will explore different approaches to approximating this number. You may assume that all inputs are as specified, so there is no need for error checking.

1. An early characterization of Euler's number, due to Jacob Bernoulli, was as the limit of

$$\left(1 + \frac{1}{x}\right)^x \tag{2}$$

as $x \to \infty$. Define a function called euler_limit that takes as its only argument an integer n, and returns a float that approximates e by taking x = n in Equation (2).

- 2. Define a function called euler_infinite_sum that takes a single non-negative integer argument n, and returns an approximation to e based on the first n terms of the sum in Equation (1). Your function should return a float. As an example, euler_infinite_sum(4) should return the sum of the first four terms in Equation 1, so that euler_infinite_sum(4) returns $1+1+1/2+1/6\approx 2.667$. Note: the sum in Equation 1 starts counting with k=0 (i.e., it is "0-indexed"), while our function starts counting with n=1 (i.e., it is "1-indexed"). euler_infinite_sum(1) should use one term from Equation (1), so that euler_infinite_sum(1) returns 1. Similarly, euler_infinite_sum(0) should return 0, since by convention an empty sum is equal to zero. Note: you may use the math.factorial function to compute k!, but I recommend, for the sake of practice, implementing the factorial function yourself, as it is a nice example of a problem that is easily solved with recursion.
- 3. Define a function called euler_approx that takes a single argument, a positive float epsilon, and returns the smallest number of terms in the sum in (1) required to obtain an approximation of e that is within epsilon of the true value of e. Hint: use a while-loop. Note: you can use the Python math module to get the true value of e (up to floating point accuracy): math.exp(1).
- 4. Define functions called print_euler_sum_table and print_euler_lim_table that each takes a single positive integer n as an argument and prints the successive values obtained from euler_infinite_sum(k) or euler_limit(k) as k ranges from 1 to n, one per line.
- 5. Which of these two approximations is better? **Note:** there is no strictly right or wrong answer to this question. I am simply asking you to think about this a bit and give a coherent argument one way or another (or at least give a brief discussion of why one might prefer one or the other).

4 Testing Properties of an Integer (3 points)

In this problem, you'll get a bit more practice working with conditionals, and a first exposure to the kind of thinking that is required in a typical "coding interview" question. An integer n is a power of 3 if $n = 3^p$ for some integer p.

1. Write a function <code>is_power_of_3</code> that takes an integer as its only argument and returns a Boolean indicating whether or not the input is a power of 3. You may assume that the input is a positive integer. You **may not** use the built-in math.sqrt

²For more on Euler's number, see https://en.wikipedia.org/wiki/E_(mathematical_constant).

- function in your solution. You should need only the division and modulus (%) operations. **Hint:** the simplest solution to this problem makes use of recursion, though recursion is not necessary.
- 2. Generalize your previous solution to a function is_power that takes as arguments a positive integer b and an integer n, in that order, and returns a Boolean. $is_power(b,n)$ should return True if n is a power of b (i.e., $n = b^p$ for some integer p) and False otherwise. You may assume that b is a positive integer and that n is an integer, so there is no need for error checking.
