STATS 701
Data Analysis using Python

Lecture 18: the UNIX/Linux Command Line
UNIX/Linux: a (very) brief history

1960s: Multics (Bell Labs, MIT, GE), a time-sharing operating system

1970s: UNIX developed at Bell Labs

1990s: GNU/Linux emerges

2000s: MacOS developed based on UNIX

The Unix philosophy: do one thing well

1. Write programs that do one thing and do it well.

2. Write programs to work together.

3. Write programs to handle text streams, because that is a universal interface.
The Unix philosophy: do one thing well

1. Write programs that do one thing and do it well.

2. Write programs to work together.

3. Write programs to handle text streams, because that is a universal interface.

These three design principles, articulated in the concise form above long after Unix was written, go a long way toward explaining how to approach the command line. For nearly any task you wish to accomplish, there almost certainly exists a way to do it (reasonably) easily by stringing together several different programs. More information: https://en.wikipedia.org/wiki/Unix_philosophy
Basic concepts

**Shell**: the program through which you interact with the computer. Provides the command line and facilitates typing commands and reading outputs. Popular shells: bash (Bourne Again Shell), csh (C Shell), ksh (Korn Shell)

**Redirect**: take the output of one program and make it the input of another. We’ll see some simple examples in a few slides.

**stdin, stdout, stderr**: three special “file handles” for reading inputs from the shell (stdin) and writing output to the shell (stderr for error messages, stdout other information).
Parts of the command line prompt

**Username:** klevin

**Hostname:** flux-hadoop-login2

**Current directory:** ~

**Prompt/delimiter:** $
Connecting to other machines: ssh

ssh (Secure Shell) network protocol allows secure communication machines
Allows remote access to resources on, e.g., a server or compute cluster

UNIX/Linux/MacOS: open a terminal, type “ssh user@machine”, and you’re off!

Windows: ssh does not come standard.
   PuTTY: https://en.wikipedia.org/wiki/PuTTY
   Cygwin: https://en.wikipedia.org/wiki/Cygwin
Typical *ssh* session

Secure shell (*ssh*) login to Fladoop, from the command line on my Mac (term)

I cropped a few security-related things out of here.

And now I have a command line prompt on the Fladoop cluster!
Secure shell (ssh) login to Fladoop, from the command line on my Mac (term)

Typical ssh session

If you’re using a Mac or UNIX/Linux machine, you can pretty much copy what I just did. On Mac, use the app Terminal. On UNIX/Linux systems, you should be able to pull up a terminal using a shortcut like ctrl+alt+t, depending on what distribution of UNIX/Linux you’re using.

On Windows, you can use cygwin to run a command line on your own machine, or use PuTTY to open an ssh connection to another machine like I did in this slide.

If you have trouble with any of this, please post to the discussion board and come to office hours to get assistance promptly so that you can do the homework.

And now I have a command line prompt on the Fladoop cluster!
Basic commands for navigating

pwd: "print/present working directory". Print the directory that you are currently in.

ls: list the contents of the current directory.

Try this. Type pwd or ls in your shell (either in terminal/cygwin or on Fladoop).

cd dirname: change the working directory to dirname.

Some special directory symbols:

~: your home directory. cd ~ will take you back to your home.
.
: the current directory. cd . will take you to where you are right now.
..: the directory above the current directory.

If you're in /home/klevin/stats, then cd .. will take you to /home/klevin.
Example: `pwd`, `ls` and `cd`

keith@Steinhaus:~$ ssh -X klevin@flux-hadoop-login.arc-ts.umich.edu
Password:

    ...

[klevin@flux-hadoop-login2 ~]$ pwd
/home/klevin
[klevin@flux-hadoop-login2 ~]$ ls
Myfile.txt  stats700f17
[klevin@flux-hadoop-login2 ~]$ cd stats700f17/
[klevin@flux-hadoop-login2 stats700f17]$ pwd
/home/klevin/stats700f17
[klevin@flux-hadoop-login2 stats700f17]$ ls .
hw1.tex  hw2.tex  hw3.tex
[klevin@flux-hadoop-login2 stats700f17]$ ls ..
myfile.txt  stats700f17
[klevin@flux-hadoop-login2 stats700f17]$ ls ~
myfile.txt  stats700f17
Getting help: man pages

When in doubt, the shell has built-in documentation, and it tends to be good!

```shell
man cmdname
```

This help page is called a man (short for manual) page. These have a reputation for being terse, but once you get used to reading them, they are extremely useful!

Some shells also have a command `apropos`:

```shell
apropos topic
```

lists all commands that might be relevant to `topic`.

Let’s read some of the `ls` man page and see if we can make sense of it.
Relevant xkcds
Basic commands: actually doing things

In the next few slides, we’ll look at some commands that actually let you do things like creating files and directories, reading files, and moving them around.

Follow along with the examples in your terminal, if you like (highly recommended).
Basic commands: echo

**echo string**: prints string to the shell.

The shell tries to interpret the exclamation point as referencing a previous command rather than as text. Escaping doesn’t do the trick here. Instead, use single-quotes to tell the shell not to try and process the string.

To print special characters (tabs, newlines, etc), use the flag `-e`, without which `echo` just prints what it’s given.
What if I want to send output someplace other than the shell?

```bash
keith@Steinhaus:~$ echo -e "hello\tworld." > myfile.txt
keith@Steinhaus:~$
```

**Note:** the other redirect, <, has a somewhat similar function, but is beyond our purposes here (stay tuned for command-line workshop at end of semester, perhaps?)

Redirect tells the shell to send the output of the program on the “greater than” side to the file on the “lesser than” side. **This creates the file on the RHS, an overwrites the old file, if it already exists!**
Basic commands: `cat`

`cat filename`: prints the contents of the file filename.

```
keith@Steinhaus:~$ cat myfile.txt
hello    world
keith@Steinhaus:~$
```

So `cat` is like `echo` but it takes a filename as argument instead of a string.
Basic commands: head

head filename: prints the first 10 lines of filename.
head -n X filename: prints the first X lines of filename.

```bash
keith@Steinhaus:~$ head ~/Teaching/Homeworks/HW1/homework1.tex
\documentclass[11pt]{article}
\usepackage{enumerate}
\usepackage{amsmath}
\usepackage{amsfonts}
\usepackage{hyperref}
\oddsidemargin 0mm
\evensidemargin 5mm
\topmargin -20mm
```

keith@Steinhaus:~$
Basic commands: more/less

more and less are two (very similar) programs for reading ASCII files.

[klevin@flux-hadoop-login2 stats700f17]$ less hw1.tex
[less takes up the whole screen]

This is just a dummy file that I wrote as an example.
An actual tex file wouldn't look like this.
It would have a bunch of stuff like
\begin{definition}
An integer $p > 1$ is called \textit{prime} is its only divisors are $1$ and $p$.
\end{definition}
and it would have a preamble section declaring its document type
and a bunch of other stuff.

Note: press “q” to quit less/more and return to the command line.
Basic commands: `mkdir`

`mkdir` dir name: creates a new directory called dir name, if it doesn’t exist

```
[klevin@flux-hadoop-login2 stats700f17]$ ls
hw1.tex  hw2.tex  hw3.tex
[klevin@flux-hadoop-login2 stats700f17]$ mkdir hadoop_stuff
[klevin@flux-hadoop-login2 stats700f17]$ ls
hadoop_stuff  hw1.tex  hw2.tex  hw3.tex
[klevin@flux-hadoop-login2 stats700f17]$ 
```
Basic commands: **mv**

**mv** file1 file2: “moves” file1 to file2, **overwriting** file2.

If file2 is a directory, this places file1 inside that directory, again replacing any existing file with the same **basename** as file1. /path/to/file/basename.txt

```
[klevin@flux-hadoop-login2 stats700f17]$ ls
hadoop_stuff  hw1.tex  hw2.tex  hw3.tex
[klevin@flux-hadoop-login2 stats700f17]$ mv hw2.tex homework2.tex
[klevin@flux-hadoop-login2 stats700f17]$ ls
hadoop_stuff  homework2.tex  hw1.tex  hw3.tex
[klevin@flux-hadoop-login2 stats700f17]$
[klevin@flux-hadoop-login2 stats700f17]$ mv hw1.tex hadoop_stuff
[klevin@flux-hadoop-login2 stats700f17]$ ls
hadoop_stuff  homework2.tex  hw3.tex
[klevin@flux-hadoop-login2 stats700f17]$ ls hadoop_stuff
Hw1.tex
[klevin@flux-hadoop-login2 stats700f17]$
```
Basic commands: \texttt{cp}

\texttt{cp} \texttt{file1} \texttt{file2}: similar to \texttt{mv}, but creates a copy of \texttt{file1} with name \texttt{file2}

So \texttt{cp} is like \texttt{mv} but \texttt{file1} is copied instead of being renamed

Note: to copy a directory, you must include the \texttt{-r} flag to \texttt{cp}: \texttt{cp -r dirname otherdirname}
Basic commands: \texttt{rm}

\texttt{rm} \texttt{filename}: deletes the file \texttt{filename}. \textbf{Be very very careful with this!}

\begin{verbatim}
[klevin@flux-hadoop-login2 stats700f17]$ ls
hadoop_stuff  homework2.tex  HW2.tex  hw3.tex
[klevin@flux-hadoop-login2 stats700f17]$ rm HW2.tex
[klevin@flux-hadoop-login2 stats700f17]$ ls
hadoop_stuff  homework2.tex  hw3.tex
[klevin@flux-hadoop-login2 stats700f17]$ 
\end{verbatim}
Basic commands: `logout`

`logout`: close connection to the current machine

```
[klevin@flux-hadoop-login2 stats700f17]$ logout
Connection to flux-hadoop-login.arc-ts.umich.edu closed.
keith@Steinhaus:~$
```

**Note:** depending on the type of shell session in use, you may need to use `exit` or `ctrl-D` to log off.
Moving files between machines: scp (Secure copy)

```
scp localfile username@hostname:path/to/file
Copy a file from your machine to some other machine via ssh

scp username@hostname:path/to/file localfile
Copy a file from another machine to your machine via ssh
```

```
keith@Steinhaus:~$ scp myfile.txt
klevin@flux-hadoop-login.arc-ts.umich.edu:~/stats700f17/myfile.txt
Password:
[authentication]
myfile.txt 100% 14 0.0KB/s 00:00
keith@Steinhaus:~$ ssh -X klevin@flux-hadoop-login.arc-ts.umich.edu
Password:
[authentication]
[klevin@flux-hadoop-login1 ~]$ ls stats700f17/
hadoop_stuff  homework2.tex  hw3.tex  myfile.txt
```
You will need `scp` for homeworks

If you are on UNIX/Linux/Mac, you can just use `scp` from the command line.

If you are on Windows, make sure you have either:

1. `cygwin` installed and working
2. `PuTTY` installed with `pscp` working

You should try and copy a file to/from Fladoop to make sure everything works.

And come talk to me if there are problems!
We’ve only scratched the surface!

The UNIX command line is extremely powerful!

Offers numerous tools for working with text and general data wrangling:
   grep, sed, awk, tr, cut, ...

Ability to use the command line is crucial to being a good “data scientist”
   Command line, once you’re good at it, makes things VERY fast!
   2-3 lines of shell script to do what would take an entire Python program!
We’ve only scratched the surface!

The UNIX command line is extremely powerful!
