Bayesian Phylogenetics 1 / 27

Who was Bayes?

- The Reverand Thomas Bayes was born in London in 1702.
- He was the son of one of the first Noncomformist ministers to be ordained in England.
- He became a Presbyterian minister in the late 1720s, but was well known for his studies of mathematics.
- He was elected a Fellow of the Royal Society of London in 1742.
- He died in 1761 before his works were published.

Bayesian Phylogenetics History Reverend Thomas Bayes 2 / 27

What is Bayes' Theorem?

- Bayes' Theorem explains how to calculate inverse probabilities.
- For example, suppose that Box B_1 contains four balls, three of which are black and one of which is white.
- Box B_2 has four balls, two of which are black and two of which are white.
- Box B_3 has four balls, one of which is black and three of which are white.

- If a ball is chosen *uniformly at random* from Box B_1 , there is a 3/4 chance that it is black.
- But if a black ball is drawn, how likely is it that it came from Box B_1 ?

Bayesian Phylogenetics

Mathematical Background

Bayes' Theorem

3 / 27

What is Bayes' Theorem?

- If a black ball is drawn, how likely is it that it came from Box B_1 ?
- To answer this question, we need to have prespecified probabilities of which box we pick to draw the ball from.
- The answer will be different if we believe a priori that Box B_1 is 10% likely to be the chosen box than if we believe that all three boxes are equally likely.
- Do the problem with a probability tree.

Bayesian Phylogenetics Mathematical Background Bayes' Theorem 4 / 27

Bayes' Theorem

• Bayes' Theorem states that if a complete list of mutually exclusive events B_1, B_2, \ldots have prior probabilities $P(B_1), P(B_2), \ldots$, and if the *likelihood* of the event A given event B_i is $P(A | B_i)$ for each i, then

$$P(B_i | A) = \frac{P(A | B_i)P(B_i)}{\sum_{j} P(A | B_j)P(B_j)}$$

• The posterior probability of B_i given A, written $P(B_i | A)$, is proportional to the product of the likelihood $P(A | B_i)$ and the prior probability $P(B_i)$ where the normalizing constant $P(A) = \sum_i P(A | B_i) P(B_i)$ is the prior probability of A.

Connection to Phylogeny

- In a Bayesian approach to phylogenetics, the boxes are like different tree topologies, only one of which is right.
- The colored balls are like site patterns, except that there are many more than two varieties and we are able to observe multiple independent draws from each box.
- Things are further complicated in that additional parameters such as branch lengths and likelihood model parameters affect the likelihood, but are also unknown.

Bayesian Phylogenetics Mathematical Background Phylogenetics 6 / 27

Prior and Posterior Distributions

- A *prior distribution* is a probability distribution on parameters *before* any data is observed.
- A *posterior distribution* is a probability distribution on parameters *after* data is observed.

Bayesian Phylogenetics Mathematical Background Distributions 7 / 27

Bayesian Methods vs. Maximum Likelihood

	Maximum Likelihood	Bayesian
Probability	Only defined	Describes everything
	in the context	that is uncertain
	of long-run	
	relative frequencies	
Parameters	Fixed and Unknown	Random
Nuisance	Optimize them	Average over them
Parameters		
Testing	p-values	Bayes' factors
Model	Likelihood	Likelihood and Prior Distribution

Bayesian Phylogenetics Mathematical Background Likelihood 8 / 27

Bayesian Phylogenetic Methods

- Let's say we want to find the posterior probability of a clade.
- Then we are interested in computing

$$\begin{array}{lcl} P(\text{clade} \, | \, \text{data}) & = & \displaystyle \sum_{\text{tree with clade}} P(\text{tree} \, | \, \text{data}) \\ \\ & = & \displaystyle \sum_{\text{tree with clade}} \frac{P(\text{data} \, | \, \text{tree})P(\text{tree})}{P(\text{data})} \end{array}$$

 But we need to know the parameters including branch lengths (params) to compute the likelihood.

$$\begin{split} &\sum_{\text{tree with clade}} P(\text{data} \mid \text{tree}) P(\text{tree}) \\ &= \sum_{\text{tree with clade}} \int P(\text{data}, \text{params} \mid \text{tree}) P(\text{tree}) \mathrm{dparams} \\ &= \sum_{\text{tree with clade}} P(\text{tree}) \int P(\text{data} \mid \text{params}, \text{tree}) P(\text{params} \mid \text{tree}) \mathrm{dparams} \end{split}$$

Bayesian Phylogenetics

Bayesian Phylogenetics

Methods

9 / 27

Bayesian Phylogenetic Methods

• So, we need to compute:

$$\frac{\sum_{\mathsf{tree}\ \mathsf{with}\ \mathsf{clade}} \mathsf{P}(\mathsf{tree}) \int \mathsf{P}(\mathsf{data} \mid \mathsf{params}, \mathsf{tree}) \mathsf{P}(\mathsf{params} \mid \mathsf{tree}) \mathrm{d}\mathsf{params}}{\mathsf{P}(\mathsf{data})}$$

- However, P(data) is generally not computable.
- Solution? Markov chain Monte Carlo.

Bayesian Phylogenetics Bayesian Phylogenetics Methods 10 / 27

Metropolis-Hastings Example

- Assume a Jukes-Cantor likelihood model for two species where we observe 50 sites, 9 of which differ.
- The likelihood for the distance d is

$$L(d) = \left(\frac{1}{4}\right)^{50} \times \left(\frac{1}{4} - \frac{1}{4}e^{-\frac{4}{3}d}\right)^{9} \times \left(\frac{1}{4} + \frac{3}{4}e^{-\frac{4}{3}d}\right)^{41}$$

• Assume a prior for d with the form

$$p(d) = \frac{\lambda}{(1+\lambda d)^2}, \quad d > 0$$

where $\lambda > 0$ is a parameter.

- This density is what you get if you take the ratio of two independent exponential random variables, one with parameter λ and one with parameter 1.
- The median is $1/\lambda$, but the mean is $+\infty$.

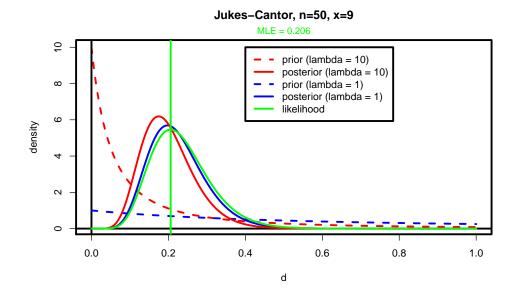

Bayesian Phylogenetics Example 11 / 27

Example

An exact expression for the posterior density of d is

$$p(d \mid x) = \frac{\left(\frac{\lambda}{(1+\lambda d)^2}\right) \left(\left(\frac{1}{4}\right)^{50} \left(\frac{1}{4} - \frac{1}{4}e^{-\frac{4}{3}d}\right)^9 \left(\frac{1}{4} + \frac{3}{4}e^{-\frac{4}{3}d}\right)^{41}\right)}{\int_0^\infty \left(\frac{\lambda}{(1+\lambda d)^2}\right) \left(\left(\frac{1}{4}\right)^{50} \left(\frac{1}{4} - \frac{1}{4}e^{-\frac{4}{3}d}\right)^9 \left(\frac{1}{4} + \frac{3}{4}e^{-\frac{4}{3}d}\right)^{41}\right) dd}$$

What is Markov Chain Monte Carlo?

- Markov chain Monte Carlo (MCMC) is a method to take (dependent) samples from a distribution.
- The distribution need only be known up to a constant of proportionality.
- MCMC is especially useful for computation of Bayesian posterior probabilities.
- Simple summary statistics from the sample converge to posterior probabilities.
- Metropolis-Hastings is a form of MCMC that works using any Markov chain to propose the next item to sample, but rejecting proposals with specified probability.

Bayesian Phylogenetics Computation MCMC 14/27

An MCMC Algorithm

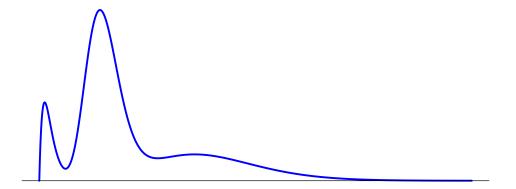

- Start at x_0 ; Set i = 0.
- 2 Propose x^* from the current x_i .
- 3 Calculate the acceptance probability.
- Generate a random number.
- - 2 If rejected, set $x_{i+1} = x_i$.
- **o** Increment i to i + 1.
- Repeat steps 2 through 6 many times.

Bayesian Phylogenetics Computation MCMC 15 / 27

Example

- We have a function $h(\theta)$ from which we want to sample.
- ullet We only need to know h up to a normalizing constant.

Bayesian Phylogenetics Computation Example 16 / 27

Initial Point

- We begin the Markov chain at a single point.
- We evaluate the value of h at this point.

Initial Point

Example

17 / 27

Proposal Distribution

Bayesian Phylogenetics

• Given our current state, we have a proposal distribution for the next candidate state.

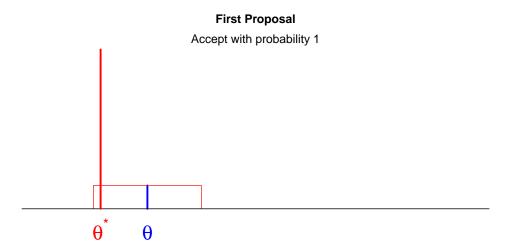

Proposal Distribution

Computation

Bayesian Phylogenetics Computation Example 18 / 27

First Proposal

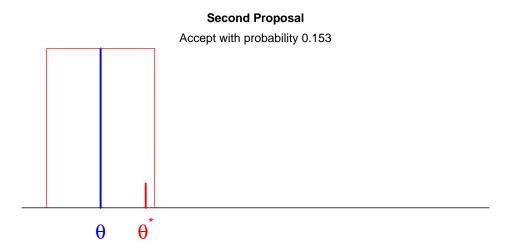

- We propose a *candidate* new point.
- Current state θ ; Proposed state θ^*
- This proposal is accepted.

Bayesian Phylogenetics Computation Example 19 / 27

Second Proposal

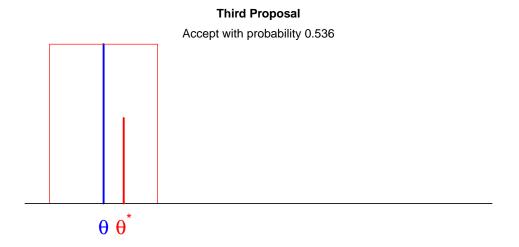

- The proposal was accepted, so proposed state becomes current.
- Current state θ ; Proposed state θ^* ; Make another proposal.
- This proposal is rejected.

Bayesian Phylogenetics Computation Example 20 / 27

Third Proposal

- The proposal was rejected, so proposed state *is sampled again* and remains current.
- Current state θ ; Proposed state θ^* ; Make another proposal.
- This proposal is accepted.

Bayesian Phylogenetics Computation Example 21 / 27

Beginning of Sample

- The first four sample points.
- Vertical position is random to separate points at the same point.

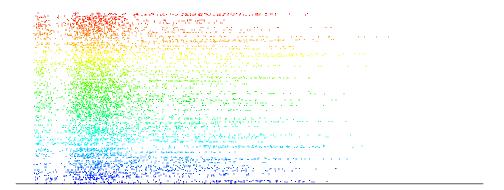

Sample So Far

Bayesian Phylogenetics Computation Example 22 / 27

Larger Sample

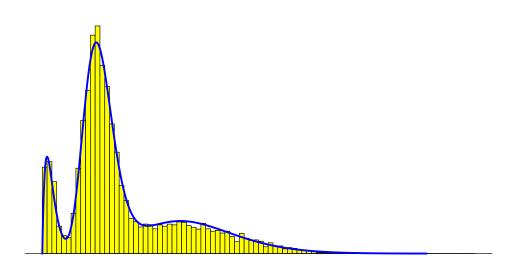

• Repeat this for 10,000 proposals and show the sample.

Large Sample

Bayesian Phylogenetics Computation Example 23 / 27

Comparison to Target

Bayesian Phylogenetics Computation Example 24 / 27

Things to Note

- The resulting sample mimics the target sample very well.
- The shape of the proposal distribution *did not depend on the target distribution at all*: almost any type of proposal method would have worked.
- There is a lot of *autocorrelation*: MCMC produces *dependent samples*.
- The acceptance probabilities depend on the proposal distributions and *relative* values of the target.
- Summaries of the sample are *good estimates* of corresponding target quantities:
 - ▶ The sample mean converges to the mean of the target.
 - ▶ The sample median converges to the median of the target.
 - ► The sample tail area above 1.0 converges to the relative area above 1.0 in the target.

Bayesian Phylogenetics Computation Example 25 / 27

MCMC for Phylogenetics

- The model parameters for a Bayesian phylogenetics analysis typically includes:
 - a tree (topology and branch lengths);
 - substitution process parameters.
- There are most often multiple MCMC methods used in combination.
- For example, methods may:
 - Adust the stationary distribution, leaving other things fixed;
 - Adjust the rates, leaving the tree fixed;
 - ► Adjust some branch lengths, leaving the topology and *Q* fixed;
 - Adjust the tree in a small region, leaving the rest of the tree fixed;
 - ▶ and so on.

Bayesian Phylogenetics MCMC for Phylogenetics 26 / 27

Cautions

- It is important to discard an initial portion of the sample as burnin.
- The MCMC sampler must be run for a long time after reaching stationarity.
- It is good practice to make several independent runs to assess agreement; chains can get stuck in local regions, leading to inaccurate inferences.
- Problems with many taxa or very long sequences are more likely to have computational problems.
